SEVERIN, S.E.

Extractable nitrogenous substances of muscle tissues in the process of ontogenesis. P. L. Vul'fson and S. E. Severin (Moscow State Univ.). Ukrains. Biokhim. Zhur. 27, 295-98 (1955) (in Russian).—Two groups of gestating sows were used. The controls were fed a standard diet. The exptl. group was given an addnl. 30% of balanced proteins and five times the vitamin A ration. At intervals embryos were removed from their mothers and qual. and quant. detns. made of the extractives of the skeletal muscles. In the early stages of the embryonic development the glutamic acid is high. It soon begins to diminish and in young pigs (one month old) it constitutes only a minor part of the N extractives of the muscles. The aspartic acid content is lower than that of glutamic acid, and it, too, diminishes as the embryo develops. The glycine content of muscle increases in the early stages up to one-month-old pigs. The content of alanine is high and remains so throughout the period of the embryo development.  $\beta$ -Alanine is high at first, but disappears in pigs one month old. At this stage the appearance of carnosine becomes manifest. By means of the diazo reagent it was shown that some carnosine is present in embryos 86 days old; in embryos 90 days old its content increases and in the skeletal muscles of piglets one month old carnosine is present to the extent of 500 mg. % on the basis of dry wt. No histidine was found. The general trend of analytical results was the same in the controls as in the richly fed animals, but the level of the data values was higher in the latter. B. S. I.

✓ Prevention of the action of poisons on the oxidative metabolism of muscle tissue by means of anserine. S. E. Severin, N. P. Meshkova, and N. I. Razumovskii (M. V. Lomonosov State Univ., Moscow). *Doklady Akad. Nauk S.S.R.* 103, 871-4(1955); cf. *C.A.* 48, 4079c, 5899b.— Expts. with pigeon breast muscle specimens in the presence of CN ions showed that addn. of anserine raises the amt. of bound P in the tissue which is proportional to the amt. of residual respiration. Carnosine does not stimulate

phosphorylation in these conditions. In expts. with NaN<sub>3</sub> it was shown that anserine almost completely prevents the toxic action of azide on respiratory phosphorylation; either carnosine or histidine added to the azide system increases O consumption and increases the formation of labile P. In the presence of dinitrophenol anserine increases only that part of phosphorylation which is not blocked by the nitrophenol.

TITLE: Some Results and Tasks of Soviet Biochemistry  
(Nekotoryye itogi i zadachi sovetskoy biokhimii).

PERIODICAL: Vestnik AN SSSR, 1957, October, Nr 10, pp. 66-70 (USSR)

ABSTRACT: The 3 most important institutes in the field of  
biochemistry are the following:  
1) The Biochemical Institute imeni A. N. Bakh AS USSR;  
2) The Institute of Medical and Biological Chemistry,  
Academy of Medical Sciences USSR3) The Ukrainian Biochemical Institute, AS Ukrainian SSR (Kiev)  
In addition a number of biochemical laboratories was  
established recently at many institutes AS USSR, at many  
research laboratories and at the universities.The following important research results are worth  
mentioning:  
a) Nitrogen change- conversion of amino acids.- Separation  
of the ferment causing aminoazation.  
b) Determination of the influence of vitamin B6.  
c) Determination of the structure and the fermentative

Card 1/3

Some Results and Tasks of Soviet Biochemistry

30-10-8/26

conditions under which various complex carbohydrates split up.

- d) Synthesis and decomposition of oligo-saccharides.
- e) Determination of the albumin nature of the ferments.
- f) Investigation on the composition of the muscular system and on the fermentative conversions taking place in this system.
- g) Biosynthesis of "carnozine".
- h) Investigation on the complicated albumina occurring in the nucleons proteides.
- i) Determination of the composition of blood and from that the determination of optimum blood conservation.
- k) Investigation of the biochemistry of the nervous system, especially of the brain.

Criticism is invited in spite of the many successes achieved. It should be pointed out that no attention at all is paid to a great number of problems. Moreover it is stated that the manufacture of laboratory instruments, glass-appliances (flasks and retorts) and chemical initial substances leaves much to be desired and that it does not by far meet the high requirements.

1126. OXIDATIVE PHOSPHORYLATION IN MUSCLE TISSUE AFTER DENERVATION OR DE-EFFERENTATION AND IN THYROTOXICOSIS (Russian text) -  
Severin S. E. Dept. of Animal Biochem., State Univ., Moscow - BIO-KHIMIIA 1957, 22/1-2 (259-265) Graphs 5

The changes in muscle metabolism observed under the above condition are not connected with the uncoupling of oxidative phosphorylation. The metabolism of muscle tissue in each investigated case had characteristic peculiarities due to a changed correlation of rates of the different enzyme reactions. An increase of ATPase activity was found in the de-efferentated muscle. In thyrotoxicosis an increased formation of fructose diphosphate was observed, which was due to the lowering of creatine kinase activity.

TITLE The Effect of Deafferentation and Defferentation of a Muscle Upon the Level of Carnosine and Anserine Contained.  
(Vlieyaniye defferentatsii i deeferentsatsii myshts na soderzha-  
niye v nikh dipeptodov kornosina i anserina -Russian)

PERIODICAL Doklady Akademii Nauk SSSR, 1957, Vol 113, Nr 2, pp 399-402 (U.S.S.R.) Received 6/1957  
Reviewed 7/1957

ABSTRACT The investigations carried out by the authors before have shown that after the elimination of motoric fibres of the nervus ischiadicus an interruption of the carbonhydrate-phosphorus conversion is observed. Considering the influence of the dipeptides ascertained before: carnosine and anserine on the mentioned conversion and of the oxidation conversion, quantity fluctuations of these dipeptides in the muscles could be assumed on the occasion of denervation. In this relation the content of these substances in deafferentiated and defferentiated muscles was investigated. It remained to be determined, which of the eliminated fibres of the nervus ischiadicus effect the quantity modifications of carnosine and anserine in the denerved muscles. For the experiments grown up cats even used; the rear roots of the spinal marrow of these cats were disjoined and the ganglia L<sub>5</sub> to S<sub>2</sub> (sometimes L<sub>4</sub>) = deafferentation, were removed. Unilateral disjunction of the front roots from L<sub>5</sub> to S<sub>2</sub> (sometimes L<sub>4</sub>) caused the defferentiation. For the investigation the calf-foot-muscles of the operated limbs were used, the

Card 1/3

The Effect of Deafferentation and Defferentation of ~~X~~XXXXXXX  
a Muscle Upon the Level of Carnosine and Anserine Contained.  
20-2-44/67

muscles symmetrical to these served as a means of control. The carnosine and anserine content was ascertained in the 3-chlorine-acetic-acid extraction by means of the distribution chromatographic method on paper. The deafferentiation of the muscles leads to a slight (18%) decrease of the carnosine content. Anserine content is apparently dependent on still smaller fluctuations. In the case of a defferentiation, the carnosine content decreases about a fortnight after the operation until it disappears entirely after 36 days. In spite of this no histidine is found in muscles. Opposing results are found for the anserine content on the occasion of deeffferentiation. After a fortnight it increases and remains increased until the 60th day. From the contrast of the results of the authors with the data from publications it becomes obvious that the fluctuations of carnosine and anserine content after a muscle-denervation depend practically only on the elimination of motoric fibres. Thus the disjunction of the rear roots of the spinal marrow together with the removal of the spinal marrow ganglia in the case of cats leads to an unessential decrease of the carnosine content; anserine content practically remains unchanged. The disjunction of the front roots of the spinal marrow causes a decrease and later even the disappearance of carnosine content. Anserine content increases and remains increased until the 60th day after the operation.

4123. EFFECTS OF THE DIPEPTIDES ANSERINE AND CARNOSINE ON OXIDATIVE PHOSPHORYLATION IN ISOLATED MITOCHONDRIA OF THE PECTORAL MUSCLE OF THE PIGEON (Russian text) - Severin S/E. and Yu Hu-Yu. Fac. of Biol., Moscow State Univ. - BIOKHIMIYA 1958. 23/6 (862-868) Graphs 2 Tables 5

$\alpha$ -Ketoglutaric acid was used as substrate and yeast hexokinase and glucose as the phosphate-accepting system. Addition of anserine to the suspension of freshly isolated mitochondria did not affect the oxygen uptake or the binding of mineral phosphate. Exposure of mitochondria to room temperature (aging) for 20, 40 and 60 min, resulted in a drastic reduction of the P/O coefficient and in swelling of the mitochondria. Addition of anserine and carnosine to the salt solution in which aging maintained phosphatase demineralization at a high level and hence prevented the reduction of the P/O coefficient. The maintenance of phosphorylation in mitochondria at a high level does not depend on the buffering capacity of the dipeptides, nor can it be attributed to a lesser rise of ATPase activity in aged mitochondria in the presence of anserine. Histidine and  $\beta$ -alanine do not exhibit any such effect as the dipeptides in question.

TITLE:

Conversions of  $\beta$ -Alanine in the Renal Tissue of Rats  
(Prevrashcheniya  $\beta$ -alanina v pochechnoy tkani krys)

PERIODICAL:

Doklady Akademii Nauk SSSR, 1958, Vol. 120, Nr 2, pp.364-367  
(USSR)

ABSTRACT:

The enzymatic decomposition of  $\beta$ -alanine had several times been investigated. Part of the authors came to the conclusion that this substance in the renal tissue is not subject to deamination (Refs 2, 3). But others (Refs 4 - 8) proved that the addition of  $\beta$ -alanine to sections or to pulp of renal periderm of rats and rabbits leads to an excessive ammonia formation and oxygen absorption. A survey of publications is given (Refs 5 - 13). The formation mechanism of ammonia at the expense of the added  $\beta$ -alanine, however, remained undetermined. The present paper is devoted to this problem. The method is described. In the first series of experiments ammonia and amino acids were determined. The authors and others (Refs 5 - 8) proved that the excessive ammonia at the ex-

Card 1/3

SOV/2o-12o-2-4o/63

Conversions of  $\beta$ -Alanine in the Renal Tissue of Rats

pense of  $\beta$ -alanine is only produced after 40 minutes of incubation. Under anaerobic conditions no ammonia forms, not even within 4 hours of incubation. But by means of the method of chromatography it was possible to observe an excessive formation of  $\beta$ -alanine and of glutamic acid after 20 minutes of incubation in an O<sub>2</sub>- or N<sub>2</sub>-atmosphere. At the same time  $\beta$ -alanine disappears (Table 1, Figure 1). The excessive formation of  $\alpha$ -amino acids and of ammonia at the expense of  $\beta$ -alanine can be explained in different manners: 1)  $\beta$ -alanine is in the renal tissue subject to an oxidative deamination; then  $\alpha$ -amino-acids form at the expense of the liberated ammonia due to amination and subsequent hyperamination. 2)  $\alpha$ -amino-acids, which are then deaminated under the formation of ammonia, are directly formed of  $\beta$ -alanine by hyperamination. 3) Both processes take place simultaneously. In order to determine which of these 3 courses is actually taken, the authors made experiments with the inhibition of aminopherases. Hydroxylamine ( $10^{-3}$ M) completely inhibited the formation of ammonia at the expense of  $\beta$ -alanine. On this occasion almost no amino acids formed (Figures 2, A and V). The hyperamination process of  $\beta$ -alanine and the formation of excessive ammonia

Card 2/3

SOV/ 2o-12o-2-4o/63

Conversions of  $\beta$ -Alanine in the Renal Tissue of Rats

were also suppressed. The experimental results speak in favor of the second hypothesis. An additional confirmation of this hypothesis was obtained with the renal pulp of rats poisoned by ING. From the above-mentioned results follows that the first stage of  $\beta$ -alanine transformation in the renal pulp of rats is the process of its hyperamination with preformed or added  $\alpha$ -ketonic acids. The formation of ammonia is the result of a subsequent deamination of the  $\alpha$ -amino-acids accumulating on this occasion. There are 3 figures, 1 table, and 19 references, 8 of which are Soviet.

TITLE: The Mechanism of Transformation of  $\beta$ -Alanine in the Renal  
Tissue of Rats (Mekhanizm prevrashcheniya  $\beta$ -alanina v po-  
chechnoy tkani krys)

PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol. 120, Nr 6, pp. 1314-1317  
(USSR)

ABSTRACT: It was found in an earlier work (Ref 1) that the formation  
of  $\text{NH}_2$  in the mentioned tissue takes place from added  $\beta$ -ala-  
nine by its reamination with a following deamination of the  
formed  $\alpha$ -amino acids. In the present paper the mechanism  
of this process is discussed. A paste from the renal cork  
layer was used for the experiment. 300 mg of it were intro-  
duced into 1,7 ml of a phosphate-salt-mixture without calcium  
ions (Ref 2). The test sample contained 20  $\mu$  mols  $\beta$ -alanine.  
The rats were prepared for the experiment by being poisoned  
with isonicotyl hydrazide (INH) (Ref 3). In the course of an  
incubation period of 4 hours in an oxygen atmosphere no ex-

Card 1/3

SOV/ 20-120-6-42/59

The Mechanism of Transformation of  $\beta$ -Alanine in the Renal Tissue of Rats

cess amount of ammonia was formed at the expense of  $\beta$ -alanine. In the control samples 9 mols of excess ammonia were accumulated within the same period (Ref 1). In the control an excess amount of  $\alpha$ -alanine and of glutamic acid was found, which had formed at the expense of the added  $\beta$ -alanine. In the test sample only an excess of  $\alpha$ -alanine was found (Figs 1, 2). These facts indicate that during the incubation  $\beta$ -alanine transfers its amino-group to the pyruvate contained in the tissue. The  $\alpha$ -alanine that forms reacts under the participation of the glutamic pyruvate transamination with the  $\alpha$ -ketoglutaric acid under formation of glutamic acid; the latter is deaminated in an  $\gamma$ -O<sub>2</sub>-atmosphere. If INH is introduced into the rats the reamination process between  $\alpha$ -alanine and  $\alpha$ -ketoglutaric acid in the renal tissue is suppressed. Due to this fact no excess glutamic acid forms at the cost of the added  $\beta$ -alanine and thus, no excess ammonia is accumulated. In order to confirm this allegation experimentally the authors carried out 4 test series: I) Reamination between  $\beta$ -alanine and pyruvate as well as between  $\beta$ -alanine and ketoglutaric acid. Table 1 shows that the expected results were obtained. II) Checking of the activity of the glutamic-

Card 2/3

SOV/ 20-120-6-42/59

The Mechanism of Transformation of  $\beta$ -Alanine in the Renal Tissue of Rats

-pyruvate-transamination. The test results proved to be in favor of the suggested hypothesis. III) Oxydative deamination of the glutamic acid. IV) Influence of INH on the cleavage of the  $\beta$ -alanine in vitro. The results are given on Tables 3 and 4. On the basis of the results obtained a cleavage mechanism of  $\beta$ -alanine in the renal tissue of rats is suggested (the scheme is given). There are 2 figures, 4 tables, and 5 references, 4 of which are Soviet.

TITLE: Characteristic Features in the Action of Dehydrase of Phosphoglycerin Aldehyde (Ob osobennostyakh deystviya degidrazy fosfoglitrinovogo al'degida)

PERIODICAL: Doklady Akademii nauk SSSR, Vol. 121, Nr 3,  
pp. 519 - 522 (USSR)

ABSTRACT: Among all factors determining the velocity of the enzymic reaction those effects which influence the suppression or the activation of the ferment are most important. We know from publications that not only substances of non-physiological nature (poisons, various synthetical compounds) but also natural transformation products may act as inhibitors. The effect of those natural products may be used to regulate the velocity of biochemical processes. The authors noticed that the activity of the dehydrase PGA depends to a great extent on the type of buffer used in connection with the reaction of the glycolytic oxide reduction. The glycine buffer had the most favorable effect on the ferment. In the veronal- and phosphate buffer the dehydrase

Card 1/3

Characteristic Features in the Action of Dehydrase  
of Phosphoglycerin Aldehyde

SOV/20-121-3-34/47

was suppressed. This suppression could be eliminated by the addition of amino acids and dipeptides. The reaction in the bicarbonate buffer which contained different amounts of phosphate enabled the authors to find out that the bicarbonate buffer suppresses the dehydrase PGA. This problem is treated in detail in the paper. The authors used a bicarbonate phosphate buffer without special activators; they did use, however, redistilled water. Table 1 A shows that the reaction depends on the concentration of inorganic phosphate. The impression is gained that higher phosphate concentrations bind the active dehydrase centers and thus prevent the reaction. An addition of histidine leads to the release of any reactive groups. Thus there is an increase of the enzymic activity and subsequently the amount of organic phosphorus, necessary for the reaction. The activating effect of the amino acid does not completely eliminate the inhibiting effect of phosphorus. Its importance may lie in the protection of dehydrase against the action of other inhibitors. As can be seen from figure 1, a part of this action apparently consists of interaction between phosphate, histidine and the active dehydrase centers. Various amino acids have different protecting

Card 2/3

Characteristic Features in the Action of Dehydrase  
of Phosphoglycerin Aldehyde

SOV/20-121-3-34/47

effects. Furthermore, the nature of the mentioned inhibition was determined. Figure 3 shows that competitive reactions between the reaction substrate and the phosphate exist. The higher the substrate concentration the stronger the inhibition. Apparently phosphoglycerin aldehyde competes with phosphate for the possession of some active centers in the protein. The activating affect of the amino acids may be due to the protection of those centers against phosphate and to the guarantee of a more rapid interaction between ferment and substrate. Figure 4 reveals that the effect of the amino acids decreases with increasing concentration of phosphoglycerin aldehyde. There are 4 figures and 15 references, 1 of which is Soviet.

TITLE: Regulation of Phosphorylating and Nonphosphorylating Oxidation  
by Hexokinase

PERIODICAL: Doklady Akademii nauk SSSR, 1959, Vol 128, Nr 3, pp 626-631  
(USSR)

ABSTRACT: Two types of biological oxidation reactions as mentioned in the title are distinguished (Refs 1-4). This phenomenon - generally called phenomenon of two oxidation ways in the respiratory chain - enforces the revision of several experiments, particularly the application of hexokinase and glucose - a system accepting the powerful phosphate ( $\sim P$ ) which is formed in phosphorylating oxidation. The present paper investigates the effect of hexokinase and glucose on the interrelation of the two oxidation ways mentioned in the title. The paper is divided into 2 sections: (1) Change - over to phosphorylating oxidation. The oxidation and phosphorylation of mitochondria in the liver of pigeon were

Card 1/3

Regulation of Phosphorylating and Nonphosphorylating  
Oxidation by Hexokinase

SOV/20-128-3-54/58

measured according to the method of reference 5. The dependence of oxidation and phosphorylation on the quantity of hexokinase in the reaction mixture is shown in figure 1. Hence it appears that hexokinase stimulates both processes. This respiratory stimulation (first proved by V. A. Engel'gardt and V. A. Belitser) disappears completely if the phosphorus and the adenyl system are excluded from the incubation mixture. Figure 2 shows the dynamics of  $\Delta P$  and  $\Delta O$  at the change in the hexokinase quantity from 0 to 0.2 units, i.e. the initiation of phosphorylating oxidation as a complement to the nonphosphorylating oxidation. (2) Change - over to nonphosphorylating oxidation. The results compiled in table 1 show that a preincubation with hexokinase and glucose without oxidation substratum makes possible the determination of the ability of a hexokinase excess of initiating nonphosphorylating oxidation. Table 2 shows the interrelation of phosphorylating and nonphosphorylating oxidation in dependence on the activity of the system accepting  $\sim P$ . The results obtained lead to the conclusion that the acceptor system hexokinase-glucose cannot be regarded as a

Card 2/3

Oxidation by Hexokinase SOV/20-128-3-54/58

"passive trap of macroerga" (powerful compounds). On the other hand, it is a regulator for the ratio of the two oxidation types mentioned. According to the concentration, it exerts 2 opposite kinds of effect on the coupling degree of oxidation and phosphorylation. The "switching" capacity of hexokinase, appearing under certain conditions, might play a part in the regulation of glycolysis and oxidative phosphorylation by this ferment in vivo (according to V. S. Il'in and co-worker, Refs 9, 10). There are 3 figures, 2 tables, and 10 references, 5 of which are Soviet.

TITLE: A Thermoregulatory Separation Between Respiration and Phosphorylation

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 131, No. 6, pp. 1447 - 1450

TEXT: There are 2 ways of oxidation in the respiratory system: a) a phosphorylating way, and b) a way independent of phosphorylation. The functional role of the way which is not connected with the formation of energy-rich phosphates has not yet been clarified. In their paper, the authors studied the oxidative mechanism of the maintenance of a constant body temperature of a warm-blooded animal (pigeon) under a short action of cold. The oxidative phosphorylation was measured on mitochondria of the musculus pectoralis and the liver by the methods of Ref. 9 (with the cooperation of L. L. Kiseleva). The intensity of oxidation *in vivo* was determined by the oxygen consumption of the pigeon (for methods see Ref. 18). The feathers of the test pigeons were removed and kept for 10-180 min in a cooling chamber at -15°. If the pigeon was kept for a while at about 15° before the

Card 1/3

A Thermoregulatory Separation Between Respiration and S/020/60/131/06/62/071  
Phosphorylation B011/B005

test, a progressive hypothermia of the body occurred after 10-20 min already. Pigeons coming from an unheated room in winter endured - even without feathers - the cooling for many hours maintaining their body temperature at 40°. With pigeons kept in the warm, this ability could be developed artificially. This was possible by cooling a pigeon down to +30-35°, then interrupting the further cooling. A pigeon treated in this way kept its temperature of 40° for several hours in the cooling chamber after 1-2 days. Fig. 1 shows a typical experiment. The investigation of such pigeons showed a rapid stimulation of oxygen consumption in cooling. The coefficient P/O (ratio between phosphorylating and nonphosphorylating oxidation), measured on mitochondria of pigeons cooled once more (Table 1), showed that the first cooling of about 15-25 min led to hypothermia, whereas in the second cooling of 2.5 hours (2 days after the first one) the pigeon remained at about 40°. Table 1 shows that oxidation in the muscle is directed in such a manner that it takes place in the nonphosphorylating way: P/O is reduced to 10/57. This investigation was carried out by Yan Fu-yuy in the authors' laboratory. Table 2 shows that oxidation was nearly fully separated from phosphorylation in a cold-trained pigeon which was cooled once more. In a pigeon cooled for the first time, the coupling of oxidation to phosphorylation is widely maintained while the body temperature decreases. Such birds die of

Card 2/3

A Thermoregulatory Separation Between Respiration and S/020/60/131/06/62/071  
Phosphorylation B011/B005

hypothermia in the cooling chamber within 20-40 min. Trained pigeons stand it for several hours. The mentioned passing over simplifies considerably the respiratory function in the maintenance of body temperature. The separation of one type of oxidation from the other one forms, besides the increased  $O_2$  consumption, a mechanism of urgent mobilization of heat. The rapidity of this separation indicates a perfect mechanism of thermoregulatory passing over of the oxidation ways within the muscles. The P/O ratio is supposed to be determined by the interaction of 2 opposite systems: a coupling and a separating system. The problem is being further investigated. There are 2 figures, 2 tables, and 18 references, 8 of which are Soviet.

AUTHORS: Severin, S. Ye, Corresponding Member AS USSR, Skulachev,  
V. P., Sivkova, V. G., Maslov, S. P.TITLE: Separation of oxidation and phosphorylation in the warming-up  
period after hypothermia

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 147, no. 6, 1962, 1489 - 1492

TEXT: Oxidation and phosphorylation were studied in the mitochondria of the pectoralis muscle of doves. The doves were cooled for 1.5 hr to -17°C, then left at room temperature to warm up to 38°C, and killed. The methods of separating mitochondria and measuring the oxidation and phosphorylation were described earlier (Sootnosheniye okisleniya i fosforilirovaniya v dykhatel'noy tsepi (Interrelations of oxidation and phosphorylation in the respiratory chain), Izd. AN SSSR, 1962; Biokhimiya, 25, 1058 (1960)). The tests showed that exclusion of phosphorylation does not affect the oxidation rate of succinic acid, but reduces markedly that of maleic acid owing to the loss in DNP in the mitochondria. The reduction in optical density from 6.9 to 5.2 and of the oxidation rate ratio between maleic and succinic acids from 0.88 to 0.21 indicate the structural change occurring

TITLE: Participation of imidazol, adenilic acid, CoA, and their acetyl derivatives in the synthesis and biosynthesis of acetylcholine

SOURCE: Biokhimiya, v. 30, no. 5, 1965, 970-979

TOPIC TAGS: biosynthesis, chemical synthesis, reaction mechanism, enzyme

ABSTRACT: Acetylimidazol (I), acetyladenilic acid (II), and acetyl CoA (III) were synthesized, and their properties were investigated, especially with respect to their possible participation in processes of enzymatic and non-enzymatic acetylation of choline (IV). The transfer of the acetyl group to IV occurs most readily with I, and is accelerated in the presence of CoA. The latter reaction probably occurs according to the following scheme:

processes. The mechanism of the participation of I in the formation of acetylcholine is discussed. The authors express their gratitude to Professor H. M. Botvinik for practical guidance and help in the chemical synthesis. Orig. art. has: 7 tables, 3 figures, and 3 equations.

## **PROCESSES AND PROSPECTIVE INDEX**

THE END

5. Resynthesis of adenosinetriphosphate acid during oxidation of  $\alpha$ -ketonic and amino acids in nuclear erythrocytes. V. A. Sevcin. *Biokhimiya* 2, 60-9 (1937).—It had previously been found that pyrotaartaric acid increases the respiration of nuclear erythrocytes by about 30-40%, with a corresponding increase in the abs. amt. of adenosinetriphosphoric acid (I). To det. whether pyrotaartaric acid is specific, several amino and  $\alpha$ -ketonic acids were tested. Some amino acids (alanine, glutamic acid) and  $\alpha$ -ketonic acids ( $\alpha$ -ketobutyric acid,  $\alpha$ -ketoglutaric acid) increase the respiration of bird erythrocytes. A simultaneous decrease in the decompon. of I is observed, which points to an increase in the resynthesis of I.

### ANTIBIOTICS

"Synthetic Medium for the Culture of Streptomyces Globisporus Strepto-  
mycini of the Strain LS-1", by V.A. Severin, and S.V. Gorskaya, All-  
Union Scientific Research Institute of Antibiotics, Antibiotiki, No 2,  
March-April 1957, pp 26-32

Streptomyces globisporus streptomycini, which produces Streptomycin,  
is capable of growing, developing, and producing an antibiotic in nutriti-  
ent media of various compositions; however, the most effective media  
have proved to be those containing corn extract and soya flour.

For intricate biochemical analysis, however, the authors found the  
synthetic seeding medium to be the most convenient. Consequently, a me-  
dium was developed consisting of : ammonium sulfate 0.4%; glucose  
2-2.5%; lactic acid 0.6%; sodium bicarbonate 1% (or anhydrous 0.35%);  
sodium chloride 0.2%; mono-potassium phosphate 0.05%; ferrous sulfate  
( $FeSO_4 \cdot 7H_2O$ ) - 0.005%; manganese sulfate ( $MnSO_4 \cdot 7H_2O$ ) - 0.005%;  
magnesium sulfate ( $MgSO_4 \cdot 7H_2O$ ) - 0.01%; and zinc sulfate ( $ZnSO_4 \cdot$   
 $7H_2O$ ) - 0.001%.
